springmvc 表单提交 controller 层需要接收 list 对象参数，但是昨天在家里弄怎么试都不成功，有知道怎么搞吗？

页面代码

```
<form action="swingAdd.html" method="post">
<hr/>
<p>id:<input type="text" name="list[0].id"/>,
root: <select name="list[0].root"><option value="false">false<option><option value="true"
selected="selected">true<option><select>,
expression:<input type="text" name="list[0].expression"/>,
validate_type:<select name="list[0].validateType"><option value="buyPrice">buyPrice<opti
n><select>,
expect:<input type="text" name="list[0].expect"/>,
or_else:<input type="text" name="list[0].orElse"/>,
child_id:<input type="text" name="list[0].child"/>。 <input type="button" onclick="addChild
this);" value="增加子节点"/>

<p>
<input type="submit" value="提交"/>
</form>
```

controller 代码

```
@RequestMapping(value = "/swingAdd", method = RequestMethod.POST)
    public String swingAdd(SwingFormList formList, Model model) {
//    System.out.println(swingList);
        return "swing/swingRule";
    }
```

SwingFormList 源码

```
public class SwingFormList {
    private List<Swing> list;

    public List<Swing> getList() {
        return list;
    }

    public void setList(List<Swing> list) {
        this.list = list;
    }
}
```

Swing 源码

```
public class Swing {
    //REQUIRED
    private String id;
```

```

private String expression;
private Validator validateType;
private String expect;
//IMPLIED
private boolean autoTrigger;
private String orElse;
private String executor;
private Swing child;
//other
private boolean root;
}

```

没拷贝 get/set方法了

页面错误信息

There was an unexpected error (type=Bad Request, status=400).

Validation failed for object='swingFormList'. Error count: 1

补充出错原因

child name 为 child_id:<input type="text" name="list[0].child"/>， 而 Swing.class.isAssignableFrom(org.org.eddy.swing.entity.Swing#child.getClass())

spring会尝试获取参数为一个字符串类型的构造函数并newInstance

org.springframework.beans.TypeConverterDelegate#convertIfNecessary(java.lang.String, java.lang.Object, java.lang.Object, java.lang.Class<T>, org.springframework.core.convert.TypeDescriptor)

```

else if (convertedValue instanceof String && !requiredType.isInstance(convertedValue)) {
    if (conversionAttemptEx == null && !requiredType.isInterface() && !requiredType.isEnum())
        try {
            Constructor<T> strCtor = requiredType.getConstructor(String.class);
            return BeanUtils.instantiateClass(strCtor, convertedValue);
        }
        catch (NoSuchMethodException ex) {
            // proceed with field lookup
        }
        if (logger.isTraceEnabled()) {
            logger.trace("No String constructor found on type [" + requiredType.getName() + "]", x);
        }
    }
    catch (Exception ex) {
        if (logger.isDebugEnabled()) {
            logger.debug("Construction via String failed for type [" + requiredType.getName() + "]",
, ex);
        }
    }
}

```

由于我没有参数为一个String对象的构造函数，导致产生了异常。
