springboot-mybatis多数据源

多数据源的目的

- 随着业务的发展，单库的形式已经无法承受高并发所带来的压力，一个项目使用多个数据库显得尤为重要，比如读写分离、主从复制

mybatis配置多数据源的方式

分包的方式

- 将不同数据源的mapper文件分开
- 读数据源

```
@Configuration
@MapperScan(basePackages="com.yechuan.dao.read",sqlSessionFactoryRef="readSqlSessionFactory")
public class ReadDataSourceConfig {
    @Primary
    @Bean(name = "readDataSource")
    @ConfigurationProperties("datasources.read")
    public DataSource readDataSource() {
        return new DruidDataSource();
    }

    @Primary
    @Bean(name = "readDataSourceTransactionManager")
    public DataSourceTransactionManager dataSourceTransactionManager(DataSource dataSo
```

```

rce) {
    return new DataSourceTransactionManager(dataSource);
}

@Primary
@Bean(name = "readSqlSessionFactory")
public SqlSessionFactory sqlSessionFactory(DataSource dataSource) throws Exception {
    SqlSessionFactoryBean sqlSessionFactoryBean = new SqlSessionFactoryBean();
    sqlSessionFactoryBean.setDataSource(dataSource);
    return sqlSessionFactoryBean.getObject();
}

@Primary
@Bean(name = "readSqlSessionTemplate")
public SqlSessionTemplate sqlSessionTemplate(SqlSessionFactory sqlSessionFactory) {
    return new SqlSessionTemplate(sqlSessionFactory);
}

}

```

- 写数据源

```

@Configuration
@MapperScan(basePackages = "com.yechuan.dao.write", sqlSessionFactoryRef = "writeSqlSessionFactory")
public class WriteDataSourceConfig {

    @Bean(name = "writeDataSource")
    @ConfigurationProperties("datasources.write")
    public DataSource writeDataSource() {
        return new DruidDataSource();
    }

    @Bean(name = "writeDataSourceTransactionManager")
    public DataSourceTransactionManager dataSourceTransactionManager(@Qualifier("writeDataSource") DataSource dataSource) {
        return new DataSourceTransactionManager(dataSource);
    }

    @Bean(name = "writeSqlSessionFactory")
    public SqlSessionFactory sqlSessionFactory(@Qualifier("writeDataSource") DataSource dataSource) throws Exception {
        SqlSessionFactoryBean sqlSessionFactoryBean = new SqlSessionFactoryBean();
        sqlSessionFactoryBean.setDataSource(dataSource);
        return sqlSessionFactoryBean.getObject();
    }

    @Bean(name = "writeSqlSessionTemplate")
    public SqlSessionTemplate sqlSessionTemplate(@Qualifier("writeSqlSessionFactory") SqlSessionFactory sqlSessionFactory) {
        return new SqlSessionTemplate(sqlSessionFactory);
    }
}

```

```
}
```

AOP

- 利用aop原理，在访问数据库之前，替换数据库实例
- 在访问数据库的时候，会访问 **AbstractRoutingDataSource**的**determineCurrentLookupKey**法来获取数据库的实例key

1. 定义一个枚举类来说明一下当前数据源实例key有哪些

```
public enum DataSourceKey {  
    READ("read"),  
    WRITE("write");  
  
    private String name;  
  
    public String getName() {  
        return name;  
    }  
  
    public void setName(String name) {  
        this.name = name;  
    }  
}  
}
```

2. 创建一个工具类来实现，存储与获取数据源key

```
public class DynamicDataSourceContextHolder {  
    /**  
     * 保证其线程安全  
     */  
    private static ThreadLocal<Object> CONTEXT HOLDER = ThreadLocal.withInitial(() -> Data  
ourceKey.READ.getName());  
    /**  
     * 存储  
     */  
    public static void setDataSourceKey(String key){  
        CONTEXT HOLDER.set(key);  
    }  
    /**  
     * 获取  
     */  
    public static Object getDataSourceKey(){  
        return CONTEXT HOLDER.get();  
    }  
    /**
```

```
* 删除
*/
public static void clearDataSourceKey(){
    CONTEXT HOLDER.remove();
}

}
```

3. 重写AbstractRoutingDataSource

```
@Slf4j
public class DynamicRoutingDataSource extends AbstractRoutingDataSource {

    @Override
    protected Object determineCurrentLookupKey() {
        log.info("当前使用的数据源是 : {}",DynamicDataSourceContextHolder.getDataSourceKey());
        return DynamicDataSourceContextHolder.getDataSourceKey();
    }

}
```

4. 配置数据源

```
@Configuration
public class DataSourceConfig {
    @Primary
    @Bean(name = "readDataSource")
    @ConfigurationProperties("datasources.read")
    public DataSource readDataSource() {
        return new DruidDataSource();
    }

    @Bean(name = "writeDataSource")
    @ConfigurationProperties("datasources.write")
    public DataSource writeDataSource() {
        return new DruidDataSource();

    }
    @Bean(name = "dynamicDataSource")
    public DataSource dynamicDataSource(@Qualifier(value = "readDataSource")DataSource re
dDataSource,@Qualifier(value = "writeDataSource")DataSource writeDataSource){
        DynamicRoutingDataSource dynamicRoutingDataSource = new DynamicRoutingDataSo
rce();
        Map<Object, Object> dataSourceMap = new HashMap<Object, Object>(2);
        dataSourceMap.put(DataSourceKey.READ.getName(),readDataSource);
        dataSourceMap.put(DataSourceKey.WRITE.getName(),writeDataSource);

        dynamicRoutingDataSource.setDefaultTargetDataSource(readDataSource);
        dynamicRoutingDataSource.setTargetDataSources(dataSourceMap);

        DynamicDataSourceContextHolder.dataSourceKeys.addAll(dataSourceMap.keySet());
    }
}
```

```

@Bean
public DataSourceTransactionManager dataSourceTransactionManager(@Qualifier(value = "dynamicDataSource") DataSource dataSource) {
    return new DataSourceTransactionManager(dataSource);
}

@Bean
public SqlSessionFactory sqlSessionFactory(@Qualifier(value = "dynamicDataSource") DataSource dataSource) throws Exception {
    SqlSessionFactoryBean sqlSessionFactoryBean = new SqlSessionFactoryBean();
    sqlSessionFactoryBean.setDataSource(dataSource);
    return sqlSessionFactoryBean.getObject();
}

@Bean
public SqlSessionTemplate sqlSessionTemplate(SqlSessionFactory sqlSessionFactory) {
    return new SqlSessionTemplate(sqlSessionFactory);
}
}

```

5. 自定义注解

```

@Target({ElementType.METHOD, ElementType.TYPE})
@Retention(RetentionPolicy.RUNTIME)
@Documented
public @interface UserDataSource {
    DataSourceKey value() default DataSourceKey.READ;
}

```

6. AOP动态切换数据源

```

@Slf4j
@Aspect
@Component
public class DynamicDataSourceAspect {

    @Before("@annotation(userDataSource))")
    public void switchDataSource(JoinPoint joinPoint, UserDataSource userDataSource){
        DynamicDataSourceContextHolder.setDataSourceKey(targetDataSource.value().getName());
        log.info("在方法 : [{}] 内切换数据源为: [{}]",
            joinPoint.getSignature(), DynamicDataSourceContextHolder.getDataSourceKey());
    }

    @After("@annotation(userDataSource))")
    public void restoreDataSource(JoinPoint joinPoint, UserDataSource userDataSource){
        DynamicDataSourceContextHolder.clearDataSourceKey();
        log.info("在方法 [{}] 执行后, 恢复数据源 [{}]",
            joinPoint.getSignature(), DynamicDataSourceContextHolder.getDataSourceKey());
    }
}

```

7. 在调用的时候使用注解即可

使用mybatis-plus与dynamic

- 鲁迅先生曾经说过我们不要自己造轮子，要使用别人的轮子

1. 导入相关依赖

```
<dependency>
    <groupId>com.baomidou</groupId>
    <artifactId>dynamic-datasource-spring-boot-starter</artifactId>
    <version>2.5.4</version>
</dependency>
<dependency>
    <groupId>com.baomidou</groupId>
    <artifactId>mybatis-plus-boot-starter</artifactId>
    <version>3.3.1.tmp</version>
</dependency>
```

2. yml配置

```
spring:
  datasource:
    dynamic:
      datasource:
        read:
          password: root
          username: root
          url: jdbc:mysql://localhost:3306/sharding_sphere_read
          driverClassName: com.mysql.jdbc.Driver
        write:
          password: root
          username: root
          url: jdbc:mysql://localhost:3306/sharding_sphere_write
          driverClassName: com.mysql.jdbc.Driver
      primary: read
      strict: true
```

3. 使用

```
@DS("write")
@Transactional(rollbackFor = Exception.class)
public void addUser( UserDto userDto) {
    userDao.insert(userDto);
}
```
