应用场景应该不多，记录一下。

poHeader 订单头，poInfo 单身。

原生 SQL

```
@Query(value =
    "select poHeader.po_num as poNum, poHeader.id as pold, sum(poInfo.po_price) as total
" +
    "from sc_po_header as poHeader " +
    "left join sc_po_info as poInfo on poHeader.id = poInfo.po_header_id " +
    "where poHeader.po_num in (?1) group by poHeader.po_num, poHeader.id", nativeQuer
= true)
List<Map<String, Object>> sumPoPriceByPoHeaderPoNums(Set<String> poNums);
```

结果:

```
"poHeaderNoMap": [
  {
    "pold": 100093,
    "poNum": "20200729",
    "total": 1000.00
  },
  {
    "pold": 100095,
    "total": null,
    "poNum": "20200730"
  }
],
```

ps: 因为现在业务可能有多个数据源的情况 sum null 不做处理
