关于solo同步GitHub失败的问题:

```
[ERROR]-[2023-03-18 10:51:14]-[org.b3log.solo.util.GitHubs:87]: Get git tree of file [README.d] failed: {"message":"Not Found","documentation_url":"https://docs.github.com/rest/reference/git#get-a-tree"}
```

```
INFO ]-[2023-03-18 04:29:48]-[org.b3log.solo.processor.SitemapProcessor:102]: Generated sitemap
INFO ]-[2023-03-18 10:51:11]-[org.b3log.solo.service.ExportService:338]: Backup all articles to LianDi.....
INFO ]-[2023-03-18 10:51:12]-[org.b3log.solo.service.ExportService:394]: Backup all articles to LianDi completed: {"msg":"","code":0}
INFO ]-[2023-03-18 10:51:12]-[org.b3log.solo.service.ExportService:394]: Backup public articles to your GitHub repo (sub-bug).....

```

作为一个有那么一丢丢完美主义的人，是不能忍受这么好的功能无法使用的，然后就开始解决问题了：

第一步，当然是ask社区了，搜了一下，相关的应该就两个帖子：

一个提问贴：[Solo github 备份失败 - 链滴 \(Id246.com\)](#)

一个是留言贴：[solo-blog 仓库同步功能回来了! - 链滴 \(Id246.com\)](#)

但是呢，都是提出了问题，没有解决问题，我也留言问了一下提问的大哥，看有没有解决，然而

D大可能精力都在思源上了，也没有来看这个bug

没办法了，只能抄起三年前的Java知识来读源码了，下载代码，导入idea，启动Server，失败!!! 气呵成

然后就是各种百度，发现是环境原因，现在Java版本都用到11了嘛???

解决了环境问题，然后启动，debug，找到备份的代码，应该是export，嗯对了，打个断点：

找到ExportService.exportGitHub,读

```
public void exportGitHub() {
    try {
        if (Latkes.RuntimeMode.DEVELOPMENT == Latkes.getRuntimeMode()) {
            return;
        }

        final JSONObject preference = optionQueryService.getPreference();
        if (null == preference) {
            return;
        }

        String pat = preference.optString(Option.ID_C_GITHUB_PAT);
        if (StringUtils.isBlank(pat)) {
            return;
        }
    }
}
```

```

}

LOGGER.log(Level.INFO, "Backup public articles to your GitHub repo [solo-blog]....");

final JSONObject mds = exportHexoMDs();
JdbcRepository.dispose();
final List<JSONObject> posts = (List<JSONObject>) mds.opt("posts");

final String tmpDir = System.getProperty("java.io.tmpdir");
final String date = DateFormatUtils.format(new Date(), "yyyyMMddHHmmss");
String localFilePath = tmpDir + File.separator + "solo-blog-repo-" + date;
final File localFile = new File(localFilePath);

final File postDir = new File(localFilePath + File.separator + "posts");
exportHexoMd(posts, postDir.getPath());

final File zipFile = ZipUtil.zip(localFile);
byte[] zipData;
try (final FileInputStream inputStream = new FileInputStream(zipFile)) {
    zipData = IOUtils.toByteArray(inputStream);
}

FileUtils.deleteQuietly(localFile);
FileUtils.deleteQuietly(zipFile);

final String clientTitle = preference.optString(Option.ID_C_BLOG_TITLE);
final String clientSubtitle = preference.optString(Option.ID_C_BLOG_SUBTITLE);

final JSONObject gitHubUser = GitHubs.getGitHubUser(pat);
if (null == gitHubUser) {
    return;
}

final String loginName = gitHubUser.optString("login");
final String repoName = "solo-blog";

boolean ok = GitHubs.createOrUpdateGitHubRepo(pat, loginName, repoName, ":writi
g_hand: " + clientTitle + " - " + clientSubtitle, Latkes.getServePath());
if (!ok) {
    return;
}

final String readme = genSoloBlogReadme(clientTitle, clientSubtitle, preference.optStr
ng(Option.ID_C_FAVICON_URL), loginName + "/" + repoName);
JdbcRepository.dispose();
ok = GitHubs.updateFile(pat, loginName, repoName, "README.md", readme.getBytes
StandardCharsets.UTF_8));
if (ok) {
    ok = GitHubs.updateFile(pat, loginName, repoName, "backup.zip", zipData);
}
if (ok) {
    LOGGER.log(Level.INFO, "Exported public articles to your repo [solo-blog]");
}
} catch (final Exception e) {

```

```

        LOGGER.log(Level.ERROR, "Exports public articles to your repo failed: " + e.getMessage
    );
    }
}

```

报错是在[GitHub.updateFile](#)里面，继续读：

```

public static boolean updateFile(final String pat, final String loginName, final String repoName
    final String filePath, final byte[] content) {
    final String fullRepoName = loginName + "/" + repoName;
    try {
        HttpResponse response = HttpRequest.get("https://api.github.com/repos/" + fullRepo
            Name + "/git/trees/master").header("Authorization", "token " + pat).
            connectionTimeout(7000).timeout(60000).header("User-Agent", Solos.USER_AGE
                T).send();
        int statusCode = response.statusCode();
        response.charset("UTF-8");
        String responseBody = response.bodyText();
        if (200 != statusCode && 409 != statusCode) {
            LOGGER.log(Level.ERROR, "Get git tree of file [" + filePath + "] failed: " + responseB
                dy);
            return false;
        }

        final JSONObject body = new JSONObject().
            put("message", ":memo: 更新博客").
            put("content", Base64.getEncoder().encodeToString(content));
        if (200 == statusCode) {
            final JSONObject responseData = new JSONObject(responseBody);
            final JSONArray tree = responseData.optJSONArray("tree");
            for (int i = 0; i < tree.length(); i++) {
                final JSONObject file = tree.optJSONObject(i);
                if (StringUtils.equals(filePath, file.optString("path"))) {
                    body.put("sha", file.optString("sha"));
                    break;
                }
            }
        }

        response = HttpRequest.put("https://api.github.com/repos/" + fullRepoName + "/con
            ents/" + filePath).header("Authorization", "token " + pat).
            connectionTimeout(7000).timeout(60000 * 2).header("User-Agent", Solos.USER_
                GENT).bodyText(body.toString()).send();
        statusCode = response.statusCode();
        response.charset("UTF-8");
        responseBody = response.bodyText();
        if (200 != statusCode && 201 != statusCode) {
            LOGGER.log(Level.ERROR, "Updates repo [" + repoName + "] file [" + filePath + "] fa
                led: " + responseBody);
            return false;
        }
        return true;
    } catch (final Exception e) {
        LOGGER.log(Level.ERROR, "Updates repo [" + repoName + "] file [" + filePath + "] fail
    
```

```
d: " + e.getMessage());
    return false;
}
}
```

嗯对，就是这报错了，断点打到87行，然后卧槽，日志报错里面不是已经写到这一行了嘛。。。稍微点不熟练了。。。好吧，继续看是什么错：

状态statusCode返回不正常，就会打印一条error日志，也就是我们看到的那一条，看一下返回的response：

嗯，404，问题已经很明朗了，可能是github的api地址变了，访问body中的地址：

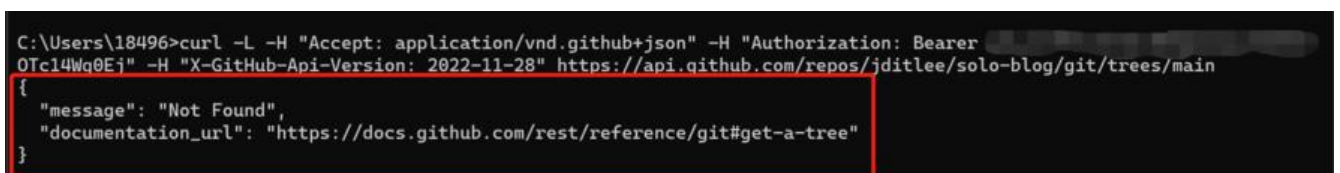

```
{\"message\": \"Not Found\", \"documentation_url\": \"https://docs.github.com/rest/reference/git#get-a-tree\"}
```

api好像没问题，自己组装curl访问一下

```
curl -L -H "Accept: application/vnd.github+json" -H "Authorization: Bearer 你的token" -H "X-GitHub-API-Version: 2022-11-28" https://api.github.com/repos/jditlee/solo-blog/git/trees/main
```

还是一样的错误

那看一下参数：

“Get a tree”的参数

标头

`accept` string

Setting to `application/vnd.github+json` is recommended.

路径参数

`owner` string 必选

The account owner of the repository. The name is not case sensitive.

`repo` string 必选

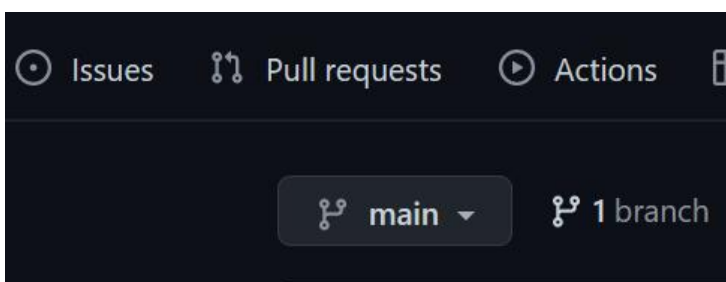

The name of the repository. The name is not case sensitive.

`tree_sha` string 必选

owner: 仓库所有者用户名

repo: 仓库名

tree_sha: 文档没说，但应该是分支，前面两个都没问题，那问题就出在分支上了，看一下代码拼接 master分支应该没问题呀，为了严谨，再看一下GitHub仓库分支：

??? 怎么会是main

从 2020 年 10 月 1 日开始，GitHub 上的所有新库都将用中性词「main」命名，取代原来的「master」，因为后者是一个容易让人联想到奴隶制的术语。

就这，好吧，问题找到了，也就知道怎么解决了：

方法一：修改分支名称为master

方法二：修改代码里面的分支为main

当然是方法一好搞一点了，改代码还要重新部署

然后呢，我为什么要写这么多废话，因为我解决这个bug浪费了很多时间，得多写一点记录一下，哈哈

告辞
